

**What is a G?**

- $\Delta U$  is the change in average internal energy.
- internal energy can be computed for individual structures
- in biomolecular simulations, internal energy is modeled by the molecular mechanics force field

- $\Delta H = \Delta U + \Delta(pV)$  is the change in enthalpy
- in biomolecular simulations, change in  $pV$  is usually negligible

- $\Delta G$  is the Gibbs free energy
  - at constant pressure and temperature, dictates
    - spontaneity and
    - equilibrium constant of process
  - in biomolecular simulation, interest in free energy differences between
    - conformations of a macromolecule
    - thermodynamic states with different temperature, pressure, volume, or other parameters
  - $\Delta G = \Delta H + T\Delta S$ , but  $\Delta S$  is very challenging to compute

# What is $\Delta G$ ?

- $\Delta U$  is the change in average internal energy.
